Testing document: How to test the view

We have written integration tests to test the view. Those integration tests will test all buttons of all view and check if they perform the correct actions when fires. Because travis can't run javaFX integration tests, we have disabled the integration tests for the maven build by renaming them so they don't end with the word "Test". If you want to run the tests with the maven build, simply rename the integration tests so they end with the word test. It is of course also possible to run the integration tests by running the test directly.

The integration tests are located in the following test package:

"src\test\java\nl\joshuaslik\tudelft\SEM\control\viewController"

The integration tests can be recognized by their name: all of them end with the letters "IT" (which stand for Integration Test).
